The Process

We based our user evaluation on the usability test dashboard, which set out a structure including; test objectives, participants, equipment, tasks, responsibilities and dates. This set out a base for us to follow when planning .

For our user evaluation we followed our customers' requirements and gathered users internally from teams working on similar projects, this guaranteed the users will be part of the target demographic, as well as being familiar with the project and its requirements, reducing setup time and improving efficiency.

To collect the data from our users we created the task list for the user to complete, these tasks included: navigating the menus, picking up power up, opening a door, finishing the level. The users were observed as they completed the tasks, and a pass or fail mark was given for each.

After the users finished testing, they were given a questionnaire with multiple opinion based questions based on their impressions on the project with a scale from 1 to 5, questions such as " I found the menus easy to navigate" were used.

The data we collected from our users were then translated into a points based system for each scenario we thought of, with higher points being higher difficulty/ more problems, this allowed us to look at the more problematic parts of the user experience and decide on the priority of the task and how easy it would be to fix. The issues found by users were categorised into different categories, allowing us to see if there is a general trend in the issues we have identified.

The data we collected from users were organised into a table, with each task being ordered with each user's pass/fail listed alongside it, and its success rate record. The questionnaire scale was added for each question, with higher points earned meaning a higher overall satisfaction. These 2 sets of data allowed us to look into the functionality of the system, as well as the designs

Usability Problems Table

As part of compiling the data gathered from prototype testing with selected participants, we collected relevant information from two forms - System Evaluation(A list of tasks that should've been completed by the user) and User Questionnaire(A set of questions the users were asked with the aim to obtain precise feedback). The table below presents identified usability problems. To evaluate the severity of each problem, we have applied the following four-tier categorisation:

1. *Cosmetic*: This problem is making it slightly difficult to complete my task.
2. *Minor*: This problem is making it difficult to complete my task.
3. *Major*: This problem is making it very difficult to complete my task
4. *Catastrophic*: This problem makes my task impossible to complete

Additionally, we have established a priority classification for each problem based on the following scale:

1. *Low*: Minor problem with does not affect functionality.
2. *Medium*: The problem causes inconvenience or minor functional issues.
3. *High*: A major feature is broken or significantly impacts user experience, but the system is still usable.
4. *Critical*: Severely affects system functionality, causes crashes, data loss, or security vulnerabilities.

Task	Problem	Potential fix	No. of users who've faced this problem	Problem Type	Priority
Move the character across the map	Found the map too big	Redesigning the map to reduce the size	2/8	Cosmetic	Low
Encountering events	Text formatting unclear in full screen	Fixing UI issues related to	3/8	Minor	Medium
Pause the game	Pause menu unclear	Redesign pause menu's UI to improve user satisfaction	2/8	Minor	Medium
Reach the end of the game	High scores don't specify usernames	Add corresponding usernames on the leaderboard	1/8	Minor	Medium
Move the character across the map	Character's speed is slow	Increase character's speed	1/8	Cosmetic	Low
Encountering events	Hidden events are hard to find/unclear	Place hidden events at more frequently visited locations	2/8	Minor	Medium
